#### Abstract

This article introduces approximately rings, approximately ideals, and approximately rings of all approximately cosets by considering new operations on the set of all approximately cosets. Afterwards, some properties of approximately rings and ideals were given.

Key words: Proximity space, relator space, descriptive approximation, approximately ring.

## 1. Introduction

Proximal relator space is a pair $\left(X, \mathcal{R}_{\delta}\right)$ that consists of a nonempty set $X$ and set of proximity relations $\mathcal{R}_{\delta}$ defined on $X$. There are different types of proximity relations such as Efremovič proximity, Wallman proximity, descriptive proximity, and Lodato proximity [1, 7, 11]. In proximal relator space, the sets consist of nonabstract points which have location and features.

The aim of this concept is to obtain algebraic structures in proximal relator spaces using descriptively upper approximations of the subsets of nonabstract points. In 2017 and 2018, approximately semigroups and approximately ideals, approximately groups, and approximately subgroups were introduced by İnan [2-4]. Approximately $\Gamma$-semigroups were also introduced [5]. In these articles some examples of these approximately algebraic structures in digital images endowed with proximity relations were given. Approximately algebraic structures satisfy a framework for further applied areas such as image analysis or classification problems. The other theories of proximity spaces were introduced by Kula [8]. In the present article an explicit characterization of the separation properties and Tychonoff objects are given in the topological category of proximity space.

Essentially, the focus of this article is to obtain approximately rings, approximately ideals, and approximately rings of all descriptive approximately cosets by considering new operations on the set of all descriptive approximately cosets. Furthermore, some properties of approximately rings and approximately ideals will be introduced.

## 2. Preliminaries

Let $X$ be a nonempty set and $\mathcal{R}$ be a family of relations on $X$. Let $\mathcal{R}$ be a family of proximity relations on $X$, then $\left(X, \mathcal{R}_{\delta}\right)$ is called proximal relator space. $\mathcal{R}_{\delta}$ contains proximity relations, for example Efremovic proximity $\delta_{E}[1]$, Lodato proximity $\delta_{\mathcal{L}}$ [7], Wallman proximity $\delta_{\omega}$, or descriptive proximity $\delta_{\Phi}$ [10, 11, 13].

[^0]Throughout this article, the Efremovič proximity [1] and the descriptive proximity relations are considered.

An Efremovič proximity $\delta$ is a relation on $P(X)$ that satisfies the following conditions:

- $A \delta B \Rightarrow B \delta A$.
- $A \delta B \Rightarrow A \neq \emptyset$ and $B \neq \emptyset$.
- $A \cap B \neq \emptyset \Rightarrow A \delta B$.
- $A \delta(B \cup C) \Leftrightarrow A \delta B$ or $A \delta C$.
- $\{x\} \delta\{y\} \Leftrightarrow x=y$.
- $A \underline{\delta} B \Rightarrow \exists E \subseteq X$ such that $A \underline{\delta} E$ and $E^{c} \underline{\delta} B$ (Efremovič Axiom).

Lodato proximity [7] swaps the Efremovic̆ Axiom with:

$$
A \delta B \text { and } \forall b \in B,\{b\} \delta C \Rightarrow A \delta C \text { (Lodato Axiom) }
$$

Let $X$ be a set of nonabstract points which has a location and features $[6, \S 3]$ in $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$. Let $\Phi=\left\{\varphi_{1}, \ldots, \varphi_{n}\right\}$ be a set of probe functions that represents features of $x \in X$.

A probe functions $\varphi_{i}: X \rightarrow \mathbb{R}$ represents features of a sample nonabstract point. Let $\Phi(x)=$ $\left(\varphi_{1}(x), \ldots, \varphi_{n}(x)\right),(n \in \mathbb{N})$ be an object description denoting a feature vector of $x$, which provides a description of each $x \in X$. After choosing a set of probe functions, one obtains a descriptive proximity relation $\delta_{\Phi}$.
[9] Let $X$ be a set of nonabstract points and $A, B \subseteq X$. The set description of $A \subseteq X$ is defined with

$$
\mathcal{Q}(A)=\{\Phi(a) \mid a \in A\}
$$

The descriptive intersection of $A$ and $B$ is defined with

$$
A \underset{\Phi}{\cap} B=\{x \in A \cup B \mid \Phi(x) \in \mathcal{Q}(A) \text { and } \Phi(x) \in \mathcal{Q}(B)\}
$$

[10] If $\mathcal{Q}(A) \cap \mathcal{Q}(B) \neq \emptyset$, then $A$ is called descriptively near or descriptively proximal to $B$. And it is denoted by $A \delta_{\Phi} B$.
[12] Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and $A \subseteq X$. Let $(A, \circ)$ and $(\mathcal{Q}(A), \cdot)$ be groupoids. Let us consider the object description $\Phi$ by means of a function

$$
\Phi: A \subseteq X \longrightarrow \mathcal{Q}(A) \subset \mathbb{R}^{n}, x \mapsto \Phi(x), x \in A
$$

The object description $\Phi$ of $A$ into $\mathcal{Q}(A)$ is an object descriptive homomorphism if $\Phi(x \circ y)=\Phi(x) \cdot \Phi(y)$ for all $x, y \in A$.

Definition 2.1 [3] Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and $A \subseteq X$. A descriptively upper approximation of $A$ is defined with

$$
\Phi^{*} A=\left\{x \in X \mid x \delta_{\Phi} A\right\}
$$

It is clear that $A \subseteq \Phi^{*} A$ for all $A \subseteq X$.

Lemma 2.2 [3] Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and $A, B$ be subsets of $X$. Then
(i) $\mathcal{Q}(A \cap B)=\mathcal{Q}(A) \cap \mathcal{Q}(B)$,
(ii) $\mathcal{Q}(A \cup B)=\mathcal{Q}(A) \cup \mathcal{Q}(B)$.

Definition 2.3 [3] Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and let "." be a binary operation on $X . G \subseteq X$ is called an approximately groupoid if $x \cdot y \in \Phi^{*} G$ for all $x, y \in G$.

Definition 2.4 [2] Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and let "." be a binary operation on $X . G \subseteq X$ is called an approximately group if the following conditions are true:
$\left(\mathcal{A} G_{1}\right) \quad x \cdot y \in \Phi^{*} G$ for all $x, y \in G$,
$\left(\mathcal{A} G_{2}\right)(x \cdot y) \cdot z=x \cdot(y \cdot z)$ property holds in $\Phi^{*} G$ for all $x, y, z \in G$,
$\left(\mathcal{A} G_{3}\right)$ There exists $e \in \Phi^{*} G$ such that $x \cdot e=e \cdot x=x$ for all $x \in G$ ( $e$ is called the approximately identity element of $G$ ),
$\left(\mathcal{A} G_{4}\right)$ There exists $y \in G$ such that $x \cdot y=y \cdot x=e$ for all $x \in G$ ( $y$ is called the inverse of $x$ in $G$ and denoted as $x^{-1}$ ).
$S \subseteq X$ is called an approximately semigroup if
$\left(\mathcal{A} S_{1}\right) x \cdot y \in \Phi^{*} S$ for all $x, y \in S$,
$\left(\mathcal{A} S_{2}\right)(x \cdot y) \cdot z=x \cdot(y \cdot z)$ property holds in $\Phi^{*} S$ for all $x, y, z \in S$
properties are satisfied.
If approximately semigroups have an approximately identity element $e \in \Phi^{*} S$ such that $x \cdot e=e \cdot x=x$ for all $x \in S$, then $S$ is called an approximately monoid.

If $x \cdot y=y \cdot x$ for all $x, y \in S$ holds in $\Phi^{*} G$, then $G$ is called commutative approximately groupoid (semigroup, monoid, or group).

Theorem 2.5 Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and $G \subseteq X$ be an approximately group. Then the following are true:
(i) There is one and only one approximately identity element in $G$.
(ii) There is one and only one inverse of elements in $G$.
(iii) If either $x \cdot z=y \cdot z$ or $z \cdot x=z \cdot y$, then $x=y$ for all $x, y, z \in G$.

Theorem 2.6 [2] Let $G$ be an approximately group, $H$ be a nonempty subset of $G$ and $\Phi^{*} H$ be a groupoid. $H$ is an approximately subgroup of $G$ if and only if $x^{-1} \in H$ for all $x \in H$.

Let $G$ be an approximately groupoid in $\left(X, \mathcal{R}_{\delta_{\Phi}}\right), x \in G$ and $A, B \subseteq G$. Then the subsets $x \cdot A, A$. $x, A \cdot B \subseteq \Phi^{*} G \subseteq X$ are defined as:

$$
\begin{gathered}
x \cdot A=x A=\{x a \mid a \in A\}, \\
A \cdot x=A x=\{a x \mid a \in A\}, \\
A \cdot B=A B=\{a b \mid a \in A, b \in B\} .
\end{gathered}
$$

Lemma 2.7 [2] Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $A, B \subseteq X$ and $A, B, \mathcal{Q}(A), \mathcal{Q}(B)$ be groupoids. If $\Phi: X \longrightarrow \mathbb{R}^{n}$ is an object descriptive homomorphism, then

$$
\mathcal{Q}(A) \mathcal{Q}(B)=\mathcal{Q}(A B)
$$

Theorem 2.8 Let $G$ be an approximately group, $H$ be an approximately subgroup of $G$ and $G / \rho_{l}$ be a set of all descriptive approximately left cosets of $G$ by $H$. If $\left(\Phi^{*} G\right) / \rho_{l} \subseteq \Phi^{*}\left(G / \rho_{l}\right)$, then $G / \rho_{l}$ is an approximately group under the operation given by $x H \odot y H=(x \cdot y) H$ for all $x, y \in G$.

## 3. Approximately rings

Definition 3.1 Let $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ be a descriptive proximal relator space and "+", "." be binary operations on $X . R \subseteq X$ is called an approximately ring if the following conditions are satisfied:
$\left(\mathcal{A} R_{1}\right) \quad R$ is an abelian approximately group with " + ",
$\left(\mathcal{A} R_{2}\right) \quad R$ is an approximately semigroup with ". ",
$\left(\mathcal{A} R_{3}\right)$ For all $x, y, z \in R, x \cdot(y+z)=(x \cdot y)+(x \cdot z)$ and $(x+y) \cdot z=(x \cdot z)+(y \cdot z)$ properties hold in $\Phi^{*} R$. In addition,
$\left(\mathcal{A} R_{4}\right)$ If $x \cdot y=y \cdot x$ for all $x, y \in R$, then $R$ is a commutative approximately ring.
$\left(\mathcal{A} R_{5}\right)$ If $\Phi^{*} R$ contains an element $1_{R}$ such that $1_{R} \cdot x=x \cdot 1_{R}=x$ for all $x \in R$,
then $R$ is called an approximately ring with identity.
These conditions have to hold in $\Phi^{*} R$. Addition or multiplying of finite number of elements in $R$ may not always belong to $\Phi^{*} R$. Therefore, we cannot always say that $n x \in \Phi^{*} R$ or $x^{n} \in \Phi^{*} R$ for all $x \in R$ and some $n \in \mathbb{Z}^{+}$. If $\left(\Phi^{*} R,+\right)$ and $\left(\Phi^{*} R, \cdot\right)$ are groupoids, then $n x \in \Phi^{*} R$ for all integer $n$ or $x^{n} \in \Phi^{*} R$ for all positive integer $n$, for all $x \in R$.

An element $x$ in approximately ring $R$ with identity is called left (resp. right) invertible if there exists $y \in R$ (resp. $z \in R$ ) such that $y \cdot x=1_{R}$ (resp. $x \cdot z=1_{R}$ ). The element $y$ (resp. $z$ ) is called a left (resp. right) inverse of $x$. If $x \in R$ is both left and right invertible, then $x$ is called approximately invertible or approximately unit. The set of approximately units in an approximately ring $R$ with identity forms is an approximately group with multiplication.

An approximately ring $R$ is an approximately division ring iff ( $R \backslash\{0\}, \cdot)$ is an approximately group, that is, each nonzero element in $R$ is an approximately unit. Moreover, an approximately ring $R$ is an approximately field iff $(R \backslash\{0\}, \cdot)$ is a commutative approximately group.

Example 3.2 Let $I$ be a digital image endowed with $\delta_{\Phi}$. I is composed of 16 pixels (image elements) as shown in the Figure 1.

An image element $x_{i j}$ is a pixel in the location $(i, j)$. Let $\varphi$ be a probe function that represents (Red, Green, Blue) RGB codes of pixels that are given in Table.

Figure 1. Digital image $I$ and subimage $R$.
Table 1. RGB codes of pixels.

|  | Red | Green | Blue |  | Red | Green | Blue |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $x_{00}$ | 193 | 202 | 253 | $x_{20}$ | 100 | 160 | 145 |
| $x_{01}$ | 193 | 202 | 253 | $x_{21}$ | 204 | 245 | 185 |
| $x_{02}$ | 100 | 160 | 145 | $x_{22}$ | 181 | 232 | 231 |
| $x_{03}$ | 204 | 245 | 185 | $x_{23}$ | 100 | 160 | 145 |
| $x_{10}$ | 237 | 198 | 169 | $x_{30}$ | 204 | 245 | 185 |
| $x_{11}$ | 237 | 198 | 169 | $x_{31}$ | 100 | 160 | 145 |
| $x_{12}$ | 204 | 245 | 185 | $x_{32}$ | 200 | 200 | 250 |
| $x_{13}$ | 100 | 160 | 145 | $x_{33}$ | 170 | 240 | 200 |

Let

$$
+: \begin{array}{ll}
I \times I & \longrightarrow I \\
\left(x_{i j}, x_{k l}\right) & \longmapsto x_{i j}+x_{k l}
\end{array}
$$

$$
x_{i j}+x_{k l}=x_{m n} \quad, i+k \equiv m(\bmod 2) \text { and } j+l \equiv n(\bmod 2)
$$

be a binary operation on $I$ such that $0 \leq i, j, k, l \leq 3$. Let $R=\left\{x_{01}, x_{10}\right\} \subseteq I$.
From Definition 2.1, descriptively upper approximation of $R$ is $\Phi^{*} R=\left\{x_{i j} \in X \mid x_{i j} \delta_{\varphi} R\right\}$. Hence, $\varphi\left(x_{i j}\right) \cap Q(R) \neq \emptyset$ such that $x_{i j} \in I, Q(R)=\left\{\varphi\left(x_{i j}\right) \mid x_{i j} \in R\right\}$. From Table,

$$
\begin{aligned}
\mathcal{Q}(R) & =\left\{\varphi\left(x_{01}\right), \varphi\left(x_{10}\right)\right\} \\
& =\{(193,202,253),(237,198,169)\} .
\end{aligned}
$$

Hence, we get $\Phi^{*} R=\left\{x_{00}, x_{01}, x_{10}, x_{11}\right\}$ as in Figure 2.
Thus, $R$ is an abelian approximately group with " $+"$ in $\left(I, \mathcal{R}_{\delta_{\Phi}}\right)$ from Definition 2.4. Furthermore, let

$$
\begin{array}{ll}
\cdot: I \times I & \longrightarrow I \\
\left(x_{i j}, x_{k l}\right) & \longmapsto x_{i j} \cdot x_{k l}=x_{p r}, p=\min \{i, k\} \text { and } r=\min \{j, l\}
\end{array}
$$

be a binary operation on $I$. Then it is obivious that $R$ is an approximately semigroup with ". "in $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$. Also for all $x_{i j}, x_{k l}, x_{m n} \in R$,

Figure 2. Descriptively upper approximation of $R$.
$x_{i j} \cdot\left(x_{k l}+x_{m n}\right)=x_{i j} \cdot x_{k l}+x_{i j} \cdot x_{m n}$ and $\left(x_{i j}+x_{k l}\right) \cdot x_{m n}=x_{i j} \cdot x_{m n}+x_{k l} \cdot x_{m n}$ properties hold in $\Phi^{*} R$. Consequently, $R$ is an approximately ring.

In addition, since for all $x_{i j}, x_{k l} \in R, x_{i j} \cdot x_{k l}=x_{k l} \cdot x_{i j}, R$ is a commutative approximately ring in digital image $I$.

Lemma 3.3 All ordinary rings in proximal relator spaces are approximately rings.
Proposition 3.4 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring and $0 \in R$. If $0 \cdot x, x \cdot 0 \in R$, then for all $x, y \in R$

- $x \cdot 0=0 \cdot x=0$,
- $x \cdot(-y)=(-x) \cdot y=-(x \cdot y)$,
- $(-x) \cdot(-y)=x \cdot y$.

Definition 3.5 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring and $S$ be $a$ nonempty subset of $R$. $S$ is called approximately subring of $R$, if $S$ is an approximately ring with binary operations"+" and ". " on approximately ring $R$.

Definition 3.6 Let $R$ be an approximately field and $S \subseteq R$. $S$ is called approximately subfield of $R$, if $S$ is an approximately field.

Theorem 3.7 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring and $\left(\Phi^{*} S,+\right)$, $\left(\Phi^{*} S, \cdot\right)$ be groupoids. A nonempty subset $S$ of $R$ is an approximately subring of $R$ iff $-x \in S$ for all $x \in S$.

Proof Let $S$ be an approximately subring of $R$. Hence, $S$ is an approximately ring and $-x \in S$ for all $x \in S$. On the other hand, let $-x \in S$ for all $x \in S$. Then since $\left(\Phi^{*} S,+\right)$ is a groupoid, $(S,+)$ is a commutative approximately group in $\left(X, \mathcal{R}_{\delta_{\Phi}}\right)$ by Theorem 2.6. From the hypothesis, since $\left(\Phi^{*} S, \cdot\right)$ is a groupoid and $S \subseteq R$, then associative condition is satisfied in $\Phi^{*} S$. Hence, $(S, \cdot)$ is an approximately semigroup. For all $x, y, z \in S \subseteq R, y+z \in \Phi^{*} S$ and $x \cdot(y+z) \in \Phi^{*} S$. Moreover, $x \cdot y+x \cdot z \in \Phi^{*} S$. Since $R$ is an approximately ring, $x \cdot(y+z)=(x \cdot y)+(x \cdot z)$ property holds in $\Phi^{*} S$. Moreover, it is clear that $(x+y) \cdot z=(x \cdot z)+(y \cdot z)$ property satisfies in $\Phi^{*} S$. Therefore, $S$ is an approximately subring of $R$.

Theorem 3.8 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, $S_{1}$ and $S_{2}$ two approximately subrings of $R$ and $\Phi^{*} S_{1}, \Phi^{*} S_{2}$ be groupoids with the binary operations " + " and ". ". If

$$
\left(\Phi^{*} S_{1}\right) \cap\left(\Phi^{*} S_{2}\right)=\Phi^{*}\left(S_{1} \cap S_{2}\right)
$$

then $S_{1} \cap S_{2}$ is an approximately subring of $R$.
Corollary 3.9 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, $\left\{S_{i} \mid i \in \Delta\right\}$ be a nonempty family of approximately subrings of $R$, and $\Phi^{*} S_{i}$ be groupoids. If

$$
\bigcap_{i \in \Delta}\left(\Phi^{*} S_{i}\right)=\Phi^{*}\left(\bigcap_{i \in \Delta} S_{i}\right)
$$

then $\bigcap_{i \in \Delta} S_{i}$ is an approximately subring of $R$.

Definition 3.10 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring and $I \subseteq R$. I is a left (right) approximately ideal of $R$ provided for all $x, y \in I$ and for all $r \in R, x+y \in \Phi^{*} I,-x \in I$ and $r \cdot x \in \Phi^{*} I \quad\left(x \cdot r \in \Phi^{*} I\right)$.

A nonempty set $I$ of an approximately ring $R$ is called an approximately ideal of $R$ if $I$ is both a left and a right approximately ideal of $R$.

There is only one trivial approximately ideal of approximately ring $R$, that is, $R$ itself. Moreover, $\{0\}$ is a trivial approximately ideal of approximately ring $R$ iff $0 \in R$.

Lemma 3.11 Every approximately ideal is an approximately subring of approximately ring $R$.

Theorem 3.12 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, $I_{1}$ and $I_{2}$ two approximately ideals of $R$ and $\Phi^{*} I_{1}, \Phi^{*} I_{2}$ be groupoids with the binary operations " + " and ". ". If

$$
\left(\Phi^{*} I_{1}\right) \cap\left(\Phi^{*} I_{2}\right)=\Phi^{*}\left(I_{1} \cap I_{2}\right)
$$

then $I_{1} \cap I_{2}$ is an approximately ideal of $R$.
Proof Let $I_{1}$ and $I_{2}$ be two approximately ideals of $R$. It is obvious that $I_{1} \cap I_{2} \subseteq R$. Consider $x, y \in I_{1} \cap I_{2}$. Since $I_{1}$ and $I_{2}$ are approximately ideals, $I_{1} \subseteq \Phi^{*} I_{1}$ and $I_{2} \subseteq \Phi^{*} I_{2}$, we have $x+y,-x, r \cdot x \in \Phi^{*} I_{1}$ and $x+y,-x, r \cdot x \in \Phi^{*} I_{2}$, that is, $x+y,-x, r \cdot x \in\left(\Phi^{*} I_{1}\right) \cap\left(\Phi^{*} I_{2}\right)$ for all $x, y \in I_{1} \cap I_{2}$ and $r \in R$. Assuming $\left(\Phi^{*} I_{1}\right) \cap\left(\Phi^{*} I_{2}\right)=\Phi^{*}\left(I_{1} \cap I_{2}\right)$, we have $x+y,-x, r \cdot x \in \Phi^{*}\left(I_{1} \cap I_{2}\right)$. From Definition 3.10, $I_{1} \cap I_{2}$ is an approximately ideal of $R$.

Corollary 3.13 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, $\left\{I_{i} \mid i \in \Delta\right\}$ be a nonempty family of approximately ideals of $R$ and $\Phi^{*} I_{i}$ be groupoids with the binary operations " + " and ". ". If

$$
\bigcap_{i \in \Delta}\left(\Phi^{*} I_{i}\right)=\Phi^{*}\left(\bigcap_{i \in \Delta} I_{i}\right)
$$

then $\bigcap_{i \in \Delta} I_{i}$ is an approximately ideal of $R$.

Let $R$ be an approximately ring and $S$ be an approximately subring of $R$. The left weak equivalence relation " $\rho_{\ell}$ " defined as

$$
x \rho_{\ell} y: \Leftrightarrow-x+y \in S \cup\{e\} .
$$

A weak class defined by relation " $\rho_{\ell}$ " is called an approximately left coset. The approximately left coset that contains the element $x \in R$ is denoted by $\tilde{x}_{\ell}$, that is,

$$
\tilde{x}_{\ell}=\{x+s \mid s \in S, x \in R, x+s \in R\} \cup\{x\} .
$$

Similarly, we can define the approximately right coset that contains the element $x \in R$ denoted by $\tilde{x}_{r}$, that is,

$$
\tilde{x}_{r}=\{s+x \mid s \in S, x \in R, s+x \in R\} \cup\{x\} .
$$

We can easily show that $\tilde{x}_{\ell}=x+S$ and $\tilde{x}_{r}=S+x$. Since $(R,+)$ is an abelian approximately group, $\tilde{x}_{\ell}=\tilde{x}_{r}$ and so we use only notation $\tilde{x}$. Then

$$
R / \rho=\{x+S \mid x \in R\}
$$

is a set of all approximately cosets of $R$ by $S$. In this case, if we consider $\Phi^{*} R$ instead of approximately ring R

$$
\left(\Phi^{*} R\right) / \rho=\left\{x+S \mid x \in \Phi^{*} R\right\}
$$

Definition 3.14 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, and $S$ be an approximately subring of $R$. For $x, y \in R$, let $x+S$ and $y+S$ be two approximately cosets that determined the elements $x$ and $y$, respectively. Then the addition of two approximately cosets determined by $x+y \in \Phi^{*} R$ can be defined as

$$
(x+y)+S=\left\{(x+y)+s \mid s \in S, x+y \in \Phi^{*} R, \quad(x+y)+s \in R\right\} \cup\{x+y\}
$$

and denoted by

$$
(x+S) \oplus(y+S)=(x+y)+S
$$

Definition 3.15 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R \subseteq X$ be an approximately ring, and $S$ be an approximately subring of $R$. For $x, y \in R$, let $x+S$ and $y+S$ be two approximately cosets that determine the elements $x$ and $y$, respectively. Then the multiplying of two approximately cosets that are determined by $x \cdot y \in \Phi^{*} R$ can be defined as

$$
(x \cdot y)+S=\left\{(x \cdot y)+s \mid s \in S, x \cdot y \in \Phi^{*} R, \quad(x \cdot y)+s \in R\right\} \cup\{x \cdot y\}
$$

and denoted by

$$
(x+S) \odot(y+S)=(x \cdot y)+S
$$

Definition 3.16 Let $R / \rho$ be a set of all approximately cosets of $R$ by $S, \xi_{\Phi}(A)$ be a descriptive approximately collections and $A \in P(X)$. Then

$$
\Phi^{*}(R / \rho)=\bigcup_{\xi_{\Phi}(A)}^{\substack{\Phi \\ R / \rho \\ \\ \neq \emptyset}} \xi_{\Phi}(A)
$$

is called upper approximation of $R / \rho$.

Theorem 3.17 Let $R \subseteq X$ be an approximately ring, $S$ be an approximately subring of $R$ and $R / \rho$ be a set of all approximately cosets of $R$ by $S$. If $\left(\Phi^{*} R\right) / \rho \subseteq \Phi^{*}(R / \rho)$, then $R / \rho$ is an approximately ring under the operations given by $(x+S) \oplus(y+S)=(x+y)+S$ and $(x+S) \odot(y+S)=(x \cdot y)+S$ for all $x, y \in R$.

Proof $\left(\mathcal{A} R_{1}\right)$ Let $\left(\Phi^{*} R\right) / \rho \subseteq \Phi^{*}(R / \rho)$. Since $R$ is an approximately ring, $(R / \rho, \oplus)$ is an abelian approximately group of all approximately cosets of $R$ by $S$ from Theorem 2.8.
$\left(\mathcal{A} R_{2}\right) \quad\left(\mathcal{A} S_{1}\right)$ Since $(R, \cdot)$ is an approximately semigroup, $x \cdot y \in \Phi^{*} R$ for all $x, y \in R$ and $(x+S) \odot(y+S)=(x \cdot y)+S \in\left(\Phi^{*} R\right) / \rho$ for all $(x+S),(y+S) \in R / \rho$. From the hypothesis, $(x+S) \odot$ $(y+S)=(x \cdot y)+S \in N_{r}(B)^{*}(R / \rho)$ for all $(x+S),(y+S) \in R / \rho$.
$\left(\mathcal{A} S_{2}\right)$ Since $(R, \cdot)$ is an approximately semigroup, associative property holds in $\Phi^{*} R$. Hence,

$$
\begin{aligned}
& ((x+S) \odot(y+S)) \odot(z+S) \\
= & ((x \cdot y)+S) \odot(z+S)=((x \cdot y) \cdot z)+S \\
= & (x \cdot(y \cdot z))+S=(x+S) \odot((y \cdot z)+S)
\end{aligned}
$$

$$
=\quad(x+S) \odot((y+S) \odot(z+S))
$$

holds in $\left(\Phi^{*} R\right) / \rho$ for all $(x+S),(y+S),(z+S) \in R / \rho$. By the hypothesis, associative property holds in $\Phi^{*}(R / \rho)$. Therefore, $(R / \rho, \odot)$ is an approximately semigroup of all approximately left cosets of $R$ by $S$.
$\left(\mathcal{A} R_{3}\right)$ Since $R$ is an approximately ring, left distributive law holds in $\Phi^{*} R$. For all $(x+S),(y+S),(z+S) \in$ $R / \rho$,

$$
\begin{aligned}
& ((x+S) \odot(y+S) \oplus(z+S)) \\
= & ((x+S) \odot((y+z)+S) \\
= & (x \cdot(y+z))+S=((x \cdot y)+(x \cdot z))+S \\
= & ((x \cdot y)+S) \oplus((x \cdot z)+S) \\
= & ((x+S) \odot(y+S)) \oplus((x+S) \odot(z+S))
\end{aligned}
$$

Hence, left distributive law holds in $\left(\Phi^{*} R\right) / \rho$. Moreover, it is clear that right distributive law is satisfied in $\left(\Phi^{*} R\right) / \rho$,
$((x+S) \oplus(y+S)) \odot(z+S)=((x+S) \odot(z+S)) \oplus((x+S) \odot(z+S))$
for all $(x+S),(y+S),(z+S) \in R / \rho$.
By the hypothesis, distributive laws are satisfied in $\Phi^{*}(R / \rho)$. Consequently, $R / \rho$ is an approximately ring.

Definition 3.18 Let $R \subseteq X$ be an approximately ring, $S$ be an approximately subring of $R$. The approximately ring $R / \rho$ is called an approximately ring of all approximately cosets of $R$ by $S$ and denoted by $R / \rho S$.

Definition 3.19 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R_{1}, R_{2} \subseteq X$ be two approximately rings and $\psi$ be a mapping from $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$. If $\psi(x+y)=\psi(x)+\psi(y)$ and $\psi(x \cdot y)=\psi(x) \cdot \psi(y)$ for all $x, y \in R_{1}$, then $\psi$ is called an approximately ring homomorphism and also, $R_{1}$ is called approximately homomorphic to $R_{2}$, denoted by $R_{1} \simeq_{n} R_{2}$. An approximately ring homomorphism $\psi$ of $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$ is called
(i) an approximately monomorphism if $\psi$ is one-to-one,
(ii) an approximately epimorphism if $\psi$ is onto,
(iii) an approximately isomorphism if $\psi$ is one-to-one and onto.

Theorem 3.20 Let $R_{1}, R_{2} \subseteq X$ be two approximately rings and $\psi$ be an approximately homomorphism of $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$. Then the following properties are true:
(i) $\psi\left(0_{R_{1}}\right)=0_{R_{2}}$, where $0_{R_{2}} \in \Phi^{*} R_{2}$ is the approximately zero of $R_{2}$.
(ii) $\psi(-x)=-\psi(x)$ for all $x \in R_{1}$.

Proof (i) Since $\psi$ is an approximately homomorphism, $\psi\left(0_{R_{1}}\right) \cdot \psi\left(0_{R_{1}}\right)=\psi\left(0_{R_{1}} \cdot 0_{R_{1}}\right)=\psi\left(0_{R_{1}}\right)=$ $\psi\left(0_{R_{1}}\right) \cdot 0_{R_{2}}$. Thus, we have $\psi\left(0_{R_{1}}\right)=0_{R_{2}}$ by the Theorem 2.5 (iii).
(ii) Let $x \in R_{1}$. Then $\psi(x)+\psi(-x)=\psi(x+(-x))=\psi\left(0_{R_{1}}\right)=0_{R_{2}}$. Moreover, it is clear that $\psi(-x)+\psi(x)=0_{R_{2}}$ for all $x \in R_{1}$. From Theorem 2.5 (ii), since $\psi(x)$ has a unique inverse, $\psi(-x)=-\psi(x)$ for all $x \in R_{1}$.

Theorem 3.21 Let $\left(X, \delta_{\Phi}\right)$ be a descriptive proximity space, $R_{1}, R_{2} \subseteq X$ be two approximately rings and $\psi$ be an approximately homomorphism of $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$ and $\Phi^{*} S$ be a groupoid. Then the following properties hold.
(i) If $S$ is an approximately subring of $R_{1}$ and $\psi\left(\Phi^{*} S\right)=\Phi^{*} \psi(S)$, then $\psi(S)=\{\psi(x) \mid x \in S\}$ is an approximately subring of $R_{2}$.
(ii) If $S$ is a commutative approximately subring $R_{1}$ and $\psi\left(\Phi^{*} S\right)=\Phi^{*} \psi(S)$, then $\psi(S)$ is a commutative approximately subring of $R_{2}$.

Proof (i) Let $S$ be an approximately subring of $R_{1}$. Then $0_{S} \in \Phi^{*} S$ and by Theorem 3.20 (i), $\psi\left(0_{S}\right)=0_{R_{2}}$, where $0_{R_{2}} \in \Phi^{*} R_{2}$. Thus, $0_{R_{2}}=\psi\left(0_{S}\right) \in \psi\left(\Phi^{*} S\right)=\Phi^{*} \psi(S)$. Hence, $\psi(S) \neq \emptyset$. Let $\psi(x) \in \psi(S), x \in S$. Since $S$ is an approximately subring of $R_{1},-x \in S \subseteq \Phi^{*} S$ for all $x \in S$. Thus, $-\psi(x)=\psi(-x) \in \psi\left(\Phi^{*} S\right)=$ $\Phi^{*} \psi(S)$ for all $\psi(x) \in \psi(S)$. Hence, by Theorem 3.7, $\psi(S)$ is an approximately subring of $R_{2}$.
(ii) Let $S$ be a commutative approximately subring and $\psi(x), \psi(y) \in \psi(S)$. We have $\psi(S)$ which is an approximately subring of $R_{2}$ by (i), that is, $\psi(S)$ is an approximately ring. Then $\psi(x) \cdot \psi(y)=\psi(x \cdot y)=$ $\psi(y \cdot x)=\psi(y) \cdot \psi(x)$ for all $\psi(x), \psi(y) \in \psi\left(R_{1}\right)$. Hence, $\psi(S)$ is a commutative approximately subring of $R_{2}$.

Definition 3.22 Let $R_{1}, R_{2} \subseteq X$ be two approximately rings in $\left(X, \delta_{\Phi}\right)$ and $\psi$ be an approximately homomorphism of $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$. The kernel of $\psi$, denoted by Ker $\psi$, is defined as

$$
\operatorname{Ker} \psi=\left\{x \in R_{1} \mid \psi(x)=0_{R_{2}}\right\} .
$$

Theorem 3.23 Let $R_{1}, R_{2} \subseteq X$ be two approximately rings in $\left(X, \delta_{\Phi}\right)$ and $\psi$ be an approximately homomorphism of $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$, $\Phi^{*}$ Ker $\psi$ be a groupoid with " + " and".". Then $\emptyset \neq K e r \psi$ is an approximately ideal of $R_{1}$.

Proof Let $x, y \in \operatorname{Ker} \psi$. Then $\psi(x+(-y))=\psi(x)+\psi(-y)=\psi(x)-\psi(y)=0_{R_{2}}-0_{R_{2}}=0_{R_{2}} \in \Phi^{*} R_{2}$ and so $x+(-y) \in \Phi^{*}(K e r \psi)$. Let $r \in R_{1}$. Then $\psi(r \cdot x)=\psi(r) \cdot \psi(x)=\psi(r) \cdot 0_{R_{2}}=0_{R_{2}} \in \Phi^{*} R_{2}$ and so $r \cdot x \in \Phi^{*}(\operatorname{Ker} \psi)$. Similarly, $x \cdot r \in \Phi^{*}(\operatorname{Ker} \psi)$. Hence, from Definition 3.10, $\operatorname{Ker} \psi$ is an approximately ideal of $R_{1}$.

Theorem 3.24 Let $R$ be an approximately ring in $\left(X, \delta_{\Phi}\right)$ and $S$ be an approximately subring of $R$. Then the mapping $\Pi: \Phi^{*} R \rightarrow \Phi^{*}(R / \rho S)$ defined by $\Pi(x)=x+S$ for all $x \in \Phi^{*} R$ is an approximately homomorphism.

Proof By definition of $\Pi$ and Definition 3.15,

$$
\begin{gathered}
\Pi(x+y)=(x+y)+S=(x+S) \oplus(y+S)=\Pi(x) \oplus \Pi(y) \\
\Pi(x \cdot y)=(x \cdot y)+S=(x+S) \odot(y+S)=\Pi(x) \odot \Pi(y)
\end{gathered}
$$

for all $x, y \in R$. As a result, from Definition $3.19 \Pi$ is an approximately homomorphism.

Definition 3.25 The approximately homomorphism $\Pi$ is called an approximately natural homomorphism from $\Phi^{*} R$ into $\Phi^{*}(R / \rho S)$.

Definition 3.26 Let $R_{1}, R_{2}$ be two approximately rings in $\left(X, \delta_{\Phi}\right)$ and $S$ be a nonempty subset of $R_{1}$. Let

$$
\chi: \Phi^{*} R_{1} \longrightarrow \Phi^{*} R_{2}
$$

be a mapping and

$$
\chi_{S}=\left.{ }^{\chi}\right|_{S}: S \longrightarrow \Phi^{*} R_{2}
$$

be a restricted mapping. If $\chi(x+y)=\chi_{S}(x+y)=\chi_{S}(x)+\chi_{S}(y)=\chi(x)+\chi(y)$ and $\chi(x \cdot y)=\chi_{S}(x \cdot y)=$ $\chi_{S}(x) \cdot \chi_{S}(y)=\chi(x) \cdot \chi(y)$ for all $x, y \in S$, then $\chi$ is called a restricted approximately homomorphism and also, $R_{1}$ is called restricted approximately homomorphic to $R_{2}$, denoted by $R_{1} \simeq_{r} R_{2}$.

Theorem 3.27 Let $R_{1}, R_{2} \subseteq X$ be two approximately rings in $\left(X, \delta_{\Phi}\right)$ and $\chi$ be an approximately homomorphism from $\Phi^{*} R_{1}$ into $\Phi^{*} R_{2}$. Let $\left(\Phi^{*} \operatorname{Ker} \chi,+\right.$ ) and ( $\left.\Phi^{*} \operatorname{Ker} \chi, \cdot\right)$ be groupoids and $\left(\Phi^{*} R_{1}\right) / \rho$ be a set of all approximately cosets of $\Phi^{*} R_{1}$ by $\operatorname{Ker} \chi$. If $\left(\Phi^{*} R_{1}\right) / \rho \subseteq \Phi^{*}\left(R_{1} / \rho \operatorname{Ker} \chi\right)$ and $\Phi^{*} \chi\left(R_{1}\right)=\chi\left(\Phi^{*} R_{1}\right)$, then

$$
R_{1} / \rho \operatorname{Ker} \chi \simeq_{r} \chi\left(R_{1}\right)
$$

Proof Since $\left(\Phi^{*} \operatorname{Ker} \chi,+\right)$ and $\left(\Phi^{*} \operatorname{Ker} \chi, \cdot\right)$ are groupoids, from Theorem 3.23Ker $\chi$ is an approximately subring of $R_{1}$. Since $\operatorname{Ker} \chi$ is an approximately subring of $R_{1}$ and $\left(\Phi^{*} R_{1}\right) / \rho \subseteq \Phi^{*}\left(R_{1} / \rho \operatorname{Ker} \chi\right)$, then $R_{1} / \rho$ Ker $\chi$ is an approximately ring of all approximately cosets of $R_{1}$ by Ker $\chi$ by Theorem 3.17. Since $\Phi^{*} \chi\left(R_{1}\right)=\chi\left(\Phi^{*} R_{1}\right), \chi\left(R_{1}\right)$ is an approximately subring of $R_{2}$. Define

$$
\begin{array}{rll}
\psi: \Phi^{*}\left(R_{1} / \rho \text { Ker } \chi\right) & \longrightarrow & \Phi^{*} \chi\left(R_{1}\right) \\
A & \longmapsto & \psi(A)= \begin{cases}\psi_{R_{1} / \rho K e r \chi}(A) & , A \in\left(\Phi^{*} R_{1}\right) / \rho \\
e_{\chi\left(R_{1}\right)} & , A \notin\left(\Phi^{*} R_{1}\right) / \rho\end{cases}
\end{array}
$$

where

$$
\begin{aligned}
\psi_{R_{1} / \rho \text { Ker } \chi}=\left.{ }^{\psi}\right|_{R_{1} / \rho \text { Ker } \chi}: R_{1} / \rho \text { Ker } \chi & \longrightarrow \Phi^{*} \chi\left(R_{1}\right) \\
x+\text { Ker } \chi & \longmapsto \psi_{R_{1} / \rho \text { Ker } \chi}(x+\text { Ker } \chi)=\chi(x)
\end{aligned}
$$

for all $x+\operatorname{Ker} \chi \in R_{1} /{ }_{\rho} \operatorname{Ker} \chi$.
Since

$$
\begin{aligned}
& x+\text { Ker } \chi=\left\{x+k \mid k \in \text { Ker } \chi, x+k \in R_{1}\right\} \cup\{x\}, \\
& y+\text { Ker } \chi=\left\{y+k^{\prime} \mid k^{\prime} \in \text { Ker } \chi, y+k^{\prime} \in R_{1}\right\} \cup\{y\}
\end{aligned}
$$

and the mapping $\chi$ is an approximately homomorphism,

$$
\begin{array}{ll} 
& x+\text { Ker } \chi=y+\text { Ker } \chi \\
\Rightarrow & x \in y+\text { Ker } \chi \\
\Rightarrow & x \in\left\{y+k^{\prime} \mid k^{\prime} \in \operatorname{Ker} \chi, y+k^{\prime} \in R_{1}\right\} \text { or } x \in\{y\} \\
\Rightarrow & x=y+k^{\prime}, y+k^{\prime} \in R_{1} \text { or } x=y \\
\Rightarrow & -y+x=(-y+y)+k^{\prime}, \text { or } \chi(x)=\chi(y) \\
\Rightarrow & -y+x=k^{\prime} \\
\Rightarrow & -y+x \in \operatorname{Ker} \chi \\
\Rightarrow & \chi(-y+x)=e_{\chi\left(R_{1}\right)} \\
\Rightarrow & \chi(-y)+\chi(x)=e_{\chi\left(R_{1}\right)} \\
\Rightarrow & -\chi(y)+\chi(x)=e_{\chi\left(R_{1}\right)} \\
\Rightarrow & \chi(x)=\chi(y) \\
\Rightarrow & \psi_{R_{1 / \rho} \operatorname{Ker} \chi}(x+\text { Ker } \chi)=\psi_{R_{1 / \rho} \text { Ker }}(y+\text { Ker } \chi)
\end{array}
$$

Therefore, $\psi_{R_{1} / \rho \text { Ker } \chi}$ is well defined.
For $A, B \in \Phi^{*}\left(R_{1} / \rho\right.$ Ker $\left.\chi\right)$, let $A=B$. Since the mapping $\psi_{R_{1} / \rho K e r \chi}$ is well defined,

$$
\begin{aligned}
\psi(A) & = \begin{cases}\psi_{R_{1} / \rho \text { Ker }}(A) & , A \in\left(\Phi^{*} R_{1}\right) / \rho \\
e_{\chi}\left(R_{1}\right) & , A \notin\left(\Phi^{*} R_{1}\right) / \rho\end{cases} \\
& = \begin{cases}\psi_{R_{1} / \rho \text { Ker }}(B) & , B \in\left(\Phi^{*} R_{1}\right) / \rho \\
e_{\chi}\left(R_{1}\right) & , B \notin\left(\Phi^{*} R_{1}\right) / \rho\end{cases} \\
& =\psi(B)
\end{aligned}
$$

Therefore, $\psi$ is well defined.
For all $x+\operatorname{Ker} \chi, y+\operatorname{Ker} \chi \in R_{1} /{ }_{\rho} \operatorname{Ker} \chi \subset \Phi^{*}\left(R_{1} /{ }_{\rho} \operatorname{Ker} \chi\right)$,

$$
\begin{aligned}
& \psi((x+\text { Ker } \chi) \oplus(y+\text { Ker } \chi)) \\
= & \psi_{R_{1} / \rho \text { Ker } \chi}((x+\text { Ker } \chi) \oplus(y+\text { Ker } \chi)) \\
= & \left.\psi_{R_{1 / \rho} \text { Ker } \chi}(x+y)+\text { Ker } \chi\right) \\
= & \chi(x+y) \\
= & \chi(x)+\chi(y) \\
= & \psi_{R_{1 / \rho} \text { Ker } \chi}(x+\text { Ker } \chi)+\psi_{R_{1 / \rho} \text { Ker } \chi}(y+\text { Ker } \chi) \\
= & \psi(x+\text { Ker } \chi)+\psi(y+\text { Ker } \chi)
\end{aligned}
$$

and

$$
\begin{aligned}
& \psi((x+\text { Ker } \chi) \odot(y+\text { Ker } \chi)) \\
= & \psi_{R_{1} / \rho \text { Ker } \chi}((x+\text { Ker } \chi) \odot(y+\text { Ker } \chi)) \\
= & \chi_{R_{1} / \rho \text { Ker }}((x \cdot y)+\text { Ker } \chi) \\
= & \chi(x \cdot y) \\
= & \chi(x) \cdot \chi(y) \\
= & \psi_{R_{1} / \rho \text { Ker }}(x+\text { Ker } \chi) \cdot \psi_{R_{1 / \rho} \text { Ker } \chi}(y+\text { Ker } \chi) \\
= & \psi(x+\text { Ker } \chi) \cdot \psi(y+\text { Ker } \chi) .
\end{aligned}
$$

Therefore, $\psi$ is a restricted approximately homomorphism by Definition 3.26. Hence, $R_{1} /{ }_{\rho} K e r \chi \simeq_{r}$ $\chi\left(R_{1}\right)$.

## 4. Conclusion

To extend this work, one could study the properties of other approximately algebraic structures arising from proximal relator spaces. Hopefully this concept provides a fundamental framework for some theoretical and applied sciences.
